## Uni IT Security Notes

### Basics

#### Security Mindset

- Focus on weaknesses, not on features
- Don't rely on the "good case"
- Anticipate what an attacker could do to a system
- Weight security against user experience and privacy

#### Security Objectives

- **Confidentiality/conf**

- Nobody but the legitimate receiver can read a message
- Third party cannot gain access to communication patterns
- **Integrity/int**: The contents of communication can't be changed
- **Authenticity/authN**
  - **Entity Authentication**: Communication partners can prove their respective identity to one another
  - **Message Authentication**: It can be verified that a message is authentic (unaltered and sent by the correct entity)
- **Authorization/authZ**
  - Service or information is only available to those who have correct access rights
  - Depends on authentication being set up
- **Non-Repudiation/nRep**: A sender cannot deny having sent a message or used a service
- **Availability/avail**: Service is available with sufficient performance
- **Access Control/ac**: Access to services and information is controlled
- **Privacy/priv**
  - Restricted access to identity-related data
  - Anonymity
  - Pseudonymity

### Attacks, Threats and Vulnerabilities

- **Attacker**: A person who has the skill and motivation to carry out an attack: The steps needed to carry out an attack
- **Vulnerability**: Some characteristics of the target that can result in a security breach
- **Threat**: Combination of an attacker, an attack vector and a vulnerability
- **Attack**: A threat that has been realized and has caused a security breach

### Threat Identification

- Define **system boundaries**: What is part of your system, what is not?
- Define **security objectives**: What is important for your system to be secure?
- **List all threats** you can think of: Brainstorming and discussion with experts
- Use **conventions**:
  - Similar threat models
  - Requirement specifications
  - How to break or circumvent the specifications
  - Note security assumptions of the system
  - Be careful with perimeter security: What if perimeter has been breached?
  - Note *possible*, but not yet exploitable vulnerabilities

## Security Frameworks

### Network Specific Threat Examples

- Remote Attacks
- Eavesdropping: Sniffing of information
- Altering information
- Spoofing
- DoS
- Session hijacking
- Viruses attacking clients
- Spam
- Phishing
- Data trails/privacy leaks

### STRIDE: Attacks on a Multi-User System

- Spoofing of Identity
- Tampering with Information
- Repudiation
- Information Disclosure
- DoS
- Escalation of Privileges

### Security policies

- Classification of system states into “allowed” and “forbidden” states
- Secure system: Is only in allowed states
- Breached system: Is in forbidden state

## Malware

- Performs unwanted functions
- Often runs without user’s consent
- Telemetry (often hidden in proprietary software behind EULAs)
- Backdoors

## Networking

### TCP Overview

- Characteristics
  - Reliable
  - Connection-Oriented
  - Full-Duplex
  - Layer atop IP
  - Connection management: Setup, Release and Abort
  - Ordered delivery (package sequence control)

- Repetition of lost packets
- End-to-End ACKs
- Checksum in header
- Identified by a 5-tuple
  - Source IP
  - Destination IP
  - Transport Protocol
  - Source Port
  - Destination Port

### TCP Connection Establishment

- Virtual connection between two systems
- 3-Way-Handshake with connection states

An example connection from the client to the server:

### IP Security Issues

- IP header doesn't have confidentiality or integrity protection
  - Faking the sender address is easy to do
  - Traffic can be analyzed by sniffing packet headers
- IP payload doesn't have confidentiality or integrity protection
  - Eavesdropping is possible by sniffing packets
- Loose coupling with lower layers:
  - Easy to divert traffic
  - Availability can be easily attacked
  - Confidentiality and integrity can't be guaranteed
- Unprotected error signaling via ICMP: Fake error messages can affect availability
- DNS is insecure; i.e. DNS spoofing

### TCP Security Issues

- TCP header doesn't have confidentiality or integrity protection
- Session hijacking
  - When sniffing session details, attacker can impersonate a peer in a TCP connection

- Attackers can guess session details and attack remotely using spoofed IP addresses
- RST attack: Attackers can reset/abort attacks by injecting packets with the RST flag
- Port scanning
  - Find out open ports
  - Determine software running on port
- SYN flooding
  - Overload system resources by initializing many connections and not pursuing them

### Port Scanning

- Objective: **Collect information**
  - Installed services
  - Software versions
  - OS
  - Firewall
- Enumeration based on port
  - Well-known ports (i.e. SSH → 22)
  - Invalid connection requests: Different way of error handling can be used to fingerprint the OS
- Possible scanning methods
  - TCP connect scan
  - Half-open scan
  - SYN-ACK scan
  - ACK scan

### TCP Protection Mechanisms

- SYN flood protection
  - Limit rate of SYN packets
  - SYN cookies (RFC 4987)
    - \* Limit resources
    - \* Half-open connections are not stored in the connection table but instead as a hash in the ISN
    - \* Only if the 3rd ACK handshake packet matches the sequence number, the connection is added to the connection table
    - \* Server does not need to maintain any state information on half-open connections: Resources can't be exhausted
- Connections are only accepted if the sequence numbers are within a certain range of acceptable values (attackers would have to sniff sequence numbers or guess them)

### Session Hijacking

- Attacker takes over existing connection between two peers

- Requirement: Attacker has to sniff or guess sequence numbers of the connection correctly

### **RST Attacks (In-Connection DoS)**

Inject packet with RST flag into ongoing connection: Connection has to be aborted immediately

### **Blind IP Spoofing**

Firewall is configured to only allow one source IP address and destination IP address ( $A \rightarrow B$ ).

To circumvent this restriction:

1. Attacker starts DoS attack on A to prevent A from sending RST packets to B
2. Attacker sends TCP connection setup packet with A's source IP address to B
3. B sends SYN+ACK packet to A, but can't respond due to DoS
4. Attacker sends TCP connection ACK packet to B with ACK matching the initial sequence number chosen by B (which has to be guessed, as B sent the SYN+ACK packet to A, not the attacker)

Only works if B uses a predictable algorithm for its ISN and packet filters aren't in place.

## **Perimeter Defense in Practice**

### **Architecture Recommendations**

- Known from medieval cities, castles etc.
- Definition of system boundary between "inside" and "outside"
- Different threat models for inside and outside
  - **Inside:** Trusted
  - **Outside:** Untrusted
- Objectives
  - Create said boundary
  - Only a defined set of communication relations is allowed
  - Special security checks
  - Limited number of interconnection points
  - Simpler to manage and audit than a completely open architecture
- Problems
  - Requires intelligent selection of system boundaries
  - May require multiple levels of perimeters
  - No system/user in the "trusted inside" can truly be trusted

## Application in Networking

- Installing security devices at the network border
- Separation of network areas into inside/outside
- Prevent sensitive information from being sent to the outside (view the system in the inside as the potential, probably unintentional attacker)
- Multiple levels can increase security
- But: Perimeter security is not sufficient on its own!
  - There will probably be additional non-secured paths into the network (i.e. `ssh -R`)
  - Some malicious traffic might look like “normal” traffic and can pass

## Stateless Packet Filter

- Access Control List (ACL): Applies set of rules to each incoming packet
- Discards (denies, blocks) or forwards (allows, permits) packets based on ACL
- Typically configured by IP and TCP/UDP header fields
- Stateless inspection: Established connections can only be detected with the ACK control flag
- Can be easy to misconfigure by forgetting essential protocols
  - DNS
  - ICMP
- Advantages
  - Fast/High throughput
  - Simple to realize
  - Software-based, can be added as a package
  - Simple to configure
- Disadvantages
  - Inflexible
  - Many attacks can only be detected using stateful filtering
  - Rules and their priorities can easily get confusing
- Default discard policy
  - Block everything which is not explicitly allowed (allowlist)
  - Issue: The security policy has to be revised for each new protocol or service
  - This rule must come last/have the lowest priority, behind all “allowing” rules

## Stateful Packet Filters

- Store connection states
- Can make decisions based on
  - TCP connections
  - UDP replies to previous outgoing packet with same IP:Port relation (“UDP Connection”)
  - Application protocol states

- Similar to application layer gates/proxy firewalls, but less intruding in communication
- Rules can be more specific than in stateless packet filters
- Rules are easier to enforce, i.e. incoming TCP packets don't have to be allowed in because they have ACK set

### **Stateful Firewalls**

- Tries to fix the problems of stateless inspection
  - Too many packets have to be allowed by default (ACK → No SYN-scanning protection)
  - Protocols like FTP or SIP, which dynamically allocate port numbers, can't be filtered securely
- Create state per TCP or UDP flow
  - Source and Destination IP:Port
  - Protocol
  - Connection state
- A packet which is not associated with a state is dropped immediately
- Packets which belong to a previously established TCP/UDP "connection" are allowed to pass without further checks
- State tables have to be cleaned up periodically to prevent resource starvation

### **Application Layer Proxies**

- Protected host during connection establishment
- Different kinds
  - Application level
  - Circuit level
  - Forward proxy (client-side)
  - Reverse proxy (server-side)

### **Application Level Gateways**

- Conversion between different application layer protocols
- Evaluation up to OSI layer 7
  - Protocol verification
  - Authentication
  - Malware scanning
  - Spam filtering
  - Attack pattern filtering
- Advantage: Security policies can be enforced at application level
- Disadvantage: Computing and memory performance requirements

### **Demilitarized Zone (DMZ)**

- **Outside world:** Global Internet

- **Outside router:** Routes packet to and from bastion host
- **Bastion host:** Proxy server and relay host
- **Inside router:** Routes packets only to and from bastion host
- **Inside (protected):** Intranet

The DMZ creates 2/3 lines of defense by the use of a stub network.

Multi-Level DMZs can create even more secure perimeter defenses:

Global Internet → Access Router and Packet Filter → Public Services Host (offers i.e. public Web services) → Screening Router and Packet filter (prevents IP spoofing) → Mail host (for external mail communication) → Bastion host (i.e. proxy for FTP and Web access) → Intranet

### Web Application Firewalls (WAFs)

- Acts on the application layer
- Is a reverse proxy
- Can protect the web server from “evil” client input
  - Cross-Site scripting
  - SQL injection: Filters out JS or SQL commands in client input by removing special symbols (i.e. <, ' etc)
  - Cookie poisoning: Stores the hash values of sent cookies
  - HTML manipulation: Encrypts URL parameters

### Intrusion Detection Systems (IDS)

- Security product that is specialized on detecting anomalies during live operation of networks and computers
  - Virus/Botnet activity
  - Suspicious network activity (malware phoning home)
- Basic Approaches
  - **Signature based:** Use attack signatures/known malicious communication activity patterns
  - **Anomaly based:** Significant deviation from previously recorded baseline activity
  - **Rule based:** Define allowed by behaviour by app-specific set of legitimate actions
- Actions
  - Send ut alarm
  - Logging
  - Blocking of known patterns
- Realization
  - Appliance
  - Integration in firewall
  - Integration into host

## Symmetric Encryption

### Symmetric Encryption Overview

**Alice:**

1. Creates message
2. Chooses key
3. Computes ciphertext
4. Send ciphertext to Bob

**Eve (Attacker):**

1. Copies ciphertext
2. Tries to guess the key

**Bob:**

1. Receives ciphertext
2. Uses key
3. Computes plaintext
4. Reads message

### Kerckhoffs' Principle

- From “La Cryptographie Militaire”
- Most important point: **The security of a crypto system must lie in the non-disclosure of the key but not in the non-disclosure of the algorithm**
- Implementation
  - Keep secret which function you used for encryption
  - But a disclosure of the set of functions should not create a problem

### Strong Algorithms

- There is no attack that can break it with less effort than a brute force attack (“complete enumeration”)
- There are so many keys that a complete search of key space is infeasible

### Crypto Attack Classes

- **Active** attacks
  - Most relevant for cryptographic protocols
  - Active interference (modification, insertion or deletion of messages)
  - Man in the middle (MITM) can receive messages and modify them on the way to the receiver
- **Passive** attacks: Pure eavesdropping, without interference with communication

## Perfect Security

Ciphertext does not give any information you don't already have about the plaintext

## One-Time-Pad

- **Vernam Cypher:** Create ciphertext by XOR addition of secret key and plaintext
- **Mauborgne:** Random key, never re-use key (“one time”)
- **Shannon:** OTP is unbreakable if key is ...
  - Truly random
  - As large
  - Never reused
  - Kept secret

## Stream Cyphers

Encryption like one-time-pad, but using pseudo-random bits instead of true random (using a **Cryptographically Secure Pseudo-Random Number Generator (CSPRNG)**)

## Cryptographically Secure Pseudo-Random Number Generators (CSPRNG)

A CSPRNG must ...

- Be unpredictable
- Be computationally infeasible to compute the next outputs

... when the initial state of the CSPRNG is not known

## Design Principles for Block Cyphers

Two methods for frustrating a statistical analysis:

- **Confusion:** The ciphertext should depend on the plaintext in such a complicated way that an attacker cannot gain any information from the ciphertext (redundancy should not be visible anymore in the ciphertext)
- **Diffusion:** Each plaintext and key bit should influence as many ciphertext bits as possible
  - Changing one bit in plaintext → Many pseudo-random changes in ciphertext
  - Changing one bit in the key → Many pseudo-random changes in ciphertext

## Feistel Networks

- Described by Horst Feistel

- Algorithm
  - Plaintext block B is divided in 2 halves
  - Derive r round key keys from key
  - Feed one half through round function F
  - Then XOR the result with the other half
  - Exchange halves
- Repeat r times

### DES (Tripple DES)

- Single DES breakable in less than 24h (complete search of key space)
- Tripple DES is still secure
- Three steps of DES on each data block using up to three keys
- Decryption in reverse sequence
- 3 independend keys are the most secure
- Three same keys can be used for (insecure) DES compatibility

### AES Key Features

- FIPS standard 197
- Key length: 128/192/256 bit
- Block size: 128 bit
- Iterative rounds of substitutions and permutation, but no Feistel structure
- 10, 12 or 14 rounds
- Blocks of 16 bytes arranged in 4x4 state matrix
- Components of the round function are invertible and independent of key
  - **Substitute Bytes:** Non-linear substitution of bytes in state
  - **Shift Rows:** Cyclic shifting of rows
  - **Min Columns:** Multiplication of state elements with a fixed 4x4 matrix M

### Modes of Operation for Block Cyphers

- Objective: Encrypt multiple plaintext blocks with the same block cypher
- Straightforward solution: blockwise encryption (“Electronic Codebook Mode”)
- Problem: Patterns in the distribution of plaintext blocks remain visible

### Cypher Block Chaining (CBC)

- Avoids telltale patterns in ciphertext
- Decryption fails if a data block is missing or corrupted
- Each data block is encrypted in relation to the previous block

### Counter Mode (CTR)

- Simple and efficient

- Random access still possible
- No issues if data block is missing
- Incrementing counter is involved in randomization per data block

## Padding

- Plaintext needs to be a full number of blocks
- If plaintext does not fill the last block completely, it must be padded before encryption
  - In order to facilitate safe decryption, the last block is always padded: For example for a block size of  $n$  bytes, there are  $1 \dots n$  bytes added to the plaintext before encryption
  - Decryption can check last bytes and strip them off correspondingly
- Always need to pad with at least one byte!
- Common methods
  - Pad with bytes of the same value as the number of padding bytes (PKCS#5; i.e. if there are three bytes to be padded, add 0x03 0x03 0x03)
  - Pad with 0x80 followed by 0x00 bytes
  - Pad with zeroes except for the last byte that indicates the number of padding bytes
  - Pad with zeroes
  - Pad with space characters (0x20)

## Key Length Considerations

- Cryptography is always a matter of complexity
  - With enough time and/or space, all schemes can theoretically be broken
  - “brute force” attacks
  - Example: 56bit keys DES can be broken in <24h since 1999
- Meanwhile
  - 128bit keys have to be replaced in the coming years
  - 192bit keys are secure in medium term
  - 256bit keys are hard to crack due to physical boundaries
- Quantum computers might be able to crack keys much more quickly
- Numbers refer to unbroken algorithms in symmetric cryptography
  - Broken algorithm is one where an  $n$  bit key can be determined trying out significantly less than  $2^n$  keys

## Message Authentication

### Message Authentication Codes (MACs)

- Objectives
  - **Integrity protection:** Prevent unauthorized manipulation of data

- **Message authentication:** Prevent unauthorized origination on behalf of others
- Idea: Compute a cryptographic checksum (MAC)
- Required Properties
  - Cannot be counterfeited; without having the sender's secret, it is too complex to ...
    - \* Find another message matching the same MAC
    - \* Construct a suitable MAC for another message
  - Even smallest changes to message cause a big change of the MAC

### General Scenario

**Alice:**

1.  $m = \text{"I love you. Alice"}$
2. Select secret key  $K$
3. Compute  $MAC_K(m)$

**Bob:**

1. Receives  $m'$
2. Selects secret key  $K$
3. Computes  $MAC_K(m')$
4. Compares computed MAC with received MAC  $\rightarrow$  Matches!

**Assertion:** If computed MAC equals the MAC included in the received message, an owner of the key (Alice) really sent this message and it was not changed on the way.

### Scenario with Modified Message

**Alice:** Same as in General Scenario

**Mallory:**

- $m = \text{"It's all over! Alice."}$

**Bob**

1. Receives  $m'$
2. Selects secret key  $K$
3. Computes  $MAC_K(m')$
4. Compares computed MAC with received MAC  $\rightarrow$  Doesn't match!
5. Ignore  $m$

### MAC Computation

- Requirements
  - Shared key  $k$  between sender and receiver
  - Hash function to create a code that changes if the message has been altered

- Using **block cypher**  $f_k$  and **hash function**  $hash$ :  $MAC(m) = f_k(hash(m))$
- Using a **key dependent cryptographic hash function**  $hash(k, m)$ :  $MAC(m) = hash(k, m)$

### Hash Function Requirements

- Weak **collision resistance**: For a given message and hash it is impossible/to complex to find another message such that the hashes match
- **One-way** property
  - Easy to compute hash
  - Impossible to find message from hash

## Asymmetric Encryption

### Public Key Cryptography

**Alice:**

1. Generates key pair  $(PK_{Alice}, SK_{Alice})$
2. Published  $PK_{Alice}$  at Trent's
3.  $c$  received  $\rightarrow$  decrypts  $m = D_{SK_{Alice}}(C)$

**Trent:**

- Stores public keys
- Provides public keys on request

**Bob:**

1. Wants to send  $m$  to Alice confidentially
2. Obtains  $PK_{Alice}$  from Trent
3. Computes  $c = E_{PK_{Alice}}(m)$
4. Sends  $c$  to Alice

### RSA Key Generation

1. Alice chooses 2 large prime numbers  $p, q$  and computes  $n = p \cdot q$ ,  $\phi(n) = (p-1)(q-1)$
2. Alice chooses an integer  $e$  with  $1 < e < \phi(n)$  that is relatively prime to  $\phi(n)$
3. Alice computes an integer  $d$  with  $1 < d < \phi(n)$  and  $d \cdot e = k \cdot \phi(n) + 1$
4. Alice publishes her public key  $PK_{Alice} = (e, n)$
5. Alice keeps her private key  $SK_{Alice} = d$  and  $p, q, \phi(n)$  secret

### RSA Encryption

1. Bob obtains  $PK_{Alice} = (e, n)$
2. Bob composes plaintext  $m \in M = \{1, 2, \dots, n-1\}$
3. Bob computes the ciphertext  $c = E_{PK_{Alice}}(m) = m^e \mod n$

4. Bob sends  $c$  to Alice

### **RSA Decryption**

Alice can obtain the plaintext message  $m$  by computing  $m = D_{SK_{Alice}}(c) = c^d \bmod n = m^{ed} \bmod n$

### **RSA Security**

- **RSA problem:** Given  $e$ ,  $n$  and  $c = m^e \bmod n$ , find  $m$ 
  - Most efficient approach to solve the RSA problem is currently the integer factorization of  $n$ : An upper limit to the complexity of the problem; can be used to derive the private key from the prime factors
  - Quantum computers will be more efficient in doing integer factorization (Shor's algorithm)
  - RSA problem and integer factorization still lack mathematical proof for their complexity
- **Organizational properties**
  - **Authenticity** of the public key  $(e, n)$
  - **Confidentiality** of the secret key  $(d, p, q)$
- **Mathematical properties**
  - **Complexity of factoring** the modulus  $n$
  - **Complexity of solving** the RSA problem
- Failure of any properties will compromise the security of the method!
